Definitions

2.0/2.0 points (graded)

Please match the following terms with the letter of their appropriate definitions.

Block

A

A. A thread will stop running until a certain condition is reached

Suspend

C

B. A thread is completely removed from the OS

Sleep

E

C. A thread decides it no longer needs to run

Preempt

D

D. One thread is running and the SysTick ISR stops running that thread

Kill

B

E. A thread will not run for a prescribed amount of time

Efficiency

2.0/2.0 points (graded)

Lab 2 implemented spinlock semaphores, and Lab 3 implemented blocking semaphores. In section 3.1 we presented cooperative spinlock semaphores that added an **OS_Suspend()** in the while loop of the **OS_Wait()** implementation, so the thread will suspend if the semaphore is equal to 0. For this problem, assume the time to switch threads (about 1us) is very small compared to the periodic interrupt used to run the scheduler (10ms).

Which of the following best describes the efficiency of the three semaphore implementations

- ☐ Blocking is better than cooperative spinlock, and cooperative spinlock is better than regular spinlock
- ☒ Blocking is about the same as cooperative spinlock, and both cooperative spinlock and blocking are better than regular spinlock ✓

- ☐ Blocking is better than both cooperative spinlock and regular spinlock, and cooperative spinlock and regular spinlock are about the same

- ☐ You can not tell without implementing them

Submit

Bounded Waiting

2.0/2.0 points (graded)

What is bounded waiting?

- ☐ When we wake up a sleeping thread we wakeup the first one we find
- ☐ There is a maximum time we will wait blocked on a resource
- ☒ Once blocked there are a finite number of threads that will capture the resource before this thread is granted permission ✓

- ☐ We are allowed to continue to run without the resource and will be given the resources when it is available.
- ☐ None of the above.

Submit

Producer/consumer

2.0/2.0 points (graded)

Consider the situation in which a FIFO queue is used to buffer data between one producer thread and a consumer thread. The producer thread generates data and then it puts the data into a FIFO. The consumer thread gets data from the FIFO and processes it. The consumer can process 1000 bytes/sec on average with a maximum of 1500 and a minimum of 500 bytes/sec. The producer generates data at a fixed rate of 750 bytes/sec. It would be very bad to lose data if the producer blocks on a full FIFO.

What will happen?

- ☐ The system could work, but the bandwidth would increase a lot if the consumer ran faster
- ☐ The system could work, but the bandwidth would increase a lot if the producer ran faster
- ☐ The system will NOT work, but it would work if the consumer ran faster
- ☐ The system will NOT work, but it would work if the producer ran faster
- ☒ If the FIFO is big enough, this system will not lose data ✓

Submit

Sleeping

2.0/2.0 points (graded)

Assume you implement sleeping as described in section 3.4 and Lab 3. There are N threads and the thread switch time is dt . A thread calls `OS_Sleep(10)`, where the units of the sleep time are ms.

What is the minimum sleep time?

☐ $10\text{ms} + dt$

☐ $N * dt$

☒ 10ms ✓

☐ $10\text{ms} + N * dt$

☐ $10\text{ms} + (N-1) * dt$

☐ $10\text{ms} - dt$

What is the maximum sleep time?

☐ $10\text{ms} + dt$

☐ $N * dt$

☐ 10ms

☐ $10\text{ms} + N * dt$

☒ $10\text{ms} + (N-1) * dt$ ✓

☐ 10ms- dt
